§

1 Introduction

Intel® Xeon Phi™ processor software is a set of software and utilities that enable functionalities of the Intel® Xeon Phi™ processor x200. This document will allow its readers to understand and utilize those features.

Please note that this document pertains only to systems containing at least one Intel® Xeon Phi™ processor x200.

1.1 Terminology

DTS	Developer Tool Set (https://access.redhat.com/documentation/en-US/Red_Hat_Developer_Toolset/3/index.html)
Upstream kernel	The Linux kernel source code from www.kernel.org
gcc	The GNU C Compiler collection
gdb	The GNU Debugger
EDAC	Error Detection and Correction infrastructure in Linux kernel, Its purpose is to detect problems with the hardware in a system running Linux.
PM	Power Management
PMU	Performance Monitoring Unit, is a set of counters used to understand events happening inside a CPU
MCDRAM	High Bandwidth memory found in the processor package.
MCE	Machine Check Exception
memkind	Helper library allows direct memory allocations in the MCDRAM.

1.2 Operating Systems Support

Intel® Xeon Phi™ processor software supports two types of operating systems:

- Linux* Kernel-based operating systems, refer to [Section 3.1](#) for more information.
- Microsoft Windows* Server 2016 TP5

§

2 Linux* Intel® Xeon Phi™ Processor Software Content

2.1 Kernel

Linux* Kernel delivered with Intel® Xeon Phi™ processor software is based on an OS distribution kernel. Intel® Xeon Phi™ processor software specific additions are patches, which enable different core functionalities of the Intel® Xeon Phi™ processor x200. These functionalities are described further in this document.

2.2 Kernel tools

Please note that the *kernel-tools* package is only delivered for Red Hat* Linux* distribution. It consists of the following tools:

cpupower - shows and sets processor power related values

turbostat - reports processor frequency and idle statistics

x86_energy_perf_policy - read or write MSR_IA32_ENERGY_PERF_BIAS

2.3 Cpu power package

Please note that the *cpupower* package is only delivered for SUSE* Linux* distribution. It consists of the following tools:

cpupower - shows and sets processor power related values

turbostat - reports processor frequency and idle statistics

2.4 The cpuid Package

Cpuid is a user space tool that provides an interface for querying information about the x86 CPU.

2.5 The hwloc Package

The *Portable Hardware Locality (hwloc)* software package provides a portable abstraction (across OS, versions, architectures, etc) of the hierarchical topology of modern architectures, including NUMA memory nodes, shared caches, processor sockets, processor cores and processing units (logical processors or "threads"). It also gathers various system attributes such as cache and memory information. It primarily aims at helping applications with gathering information about modern computing hardware so as to utilize it accordingly and efficiently. *Hwloc* may display the topology in multiple convenient formats. It also offers a powerful programming interface (C API) to gather information about the hardware, bind processes, and much more.

2.6 The mcelog Package

mcelog is a utility that collects and decodes Machine Check Exception data on x86-32 and x86-64 systems. It can be run either as a daemon, or by *cron*. More detailed information about *mcelog* can be found at <http://www.mcelog.org/>

2.7 The memkind Library

The *memkind* library is a user-extensible heap manager, designed to provide efficient allocation mechanism for multithreaded applications and support for high bandwidth memory (MCDRAM). The *memkind* library is built on top of *jemalloc* and enables partitioning of the heap between kinds of memory in NUMA-capable systems.

There are several strategies (*memkind kinds*) of heap management provided out-of-the-box by the library, such as allocating from standard or high bandwidth memory, as well as using standard or huge pages (both 2 MB and 1 GB sizes).

Heap management strategy can be adjusted either by using one of the predefined *kinds* exemplified above, or user-created ones, which address application specific needs. More information about the predefined *kinds* and creating custom ones can be found in the *memkind* manual (sections KINDS and MEMKIND OPERATIONS) and *memkind* examples ("*new_kind_example.c*").

The *memkind* library provides full compatibility with ISO C standard APIs.

The high bandwidth memory interface (*hbwmalloc* API) is a set of standard heap management functions such as *malloc*, *calloc*, *realloc* and *free*, prefixed by *hbw_**. This API also provides *hbwmalloc_allocator* class compatible with the C++ standard library allocator concepts, and features policy that determines behavior when there is not enough free high bandwidth memory to satisfy a user's request. To find out more about the *hbwmalloc* API please refer to its man page.

The standard *memkind* API provides a set of standard heap management functions, each one prefixed by *memkind_** and with additional parameter to specify the *kind*. The standard API also includes functionality for *kind* management, error handling and debugging. To find out more about the *memkind* API please refer to its man page.

More information about installing and using the *memkind* library can be found in its README file.

The source code repositories, and additional information can be found at <http://memkind.github.io/memkind/>

2.8 The micperf Package

Micperf is designed to incorporate a variety of benchmarks into a simple user experience with a single interface for execution and a unified means of data inspection. The user interface consists of five executables: one for execution of benchmarks (*micprun*), and four that interpret the output of the first one. The results can be displayed as professional quality plots, human readable text or comma separated value output that can be easily imported into a variety of other applications.

The *micprun* executable, the primary application in the *micperf* package, executes six benchmarks: MKL [3] SMP Linpack [4], MKL SGEMM, MKL DGEMM, SHOC [5]

download, SHOC readback, and STREAM [6], [7]. These benchmarks were carefully chosen to demonstrate performance in all of the major bottlenecks in the system.

2.9 The *systools-sb* Package

Systools-sb package contains *SysDiag* tool which provide a variety of information and diagnostics for the processor. Please note that *systools-sb* requires *threadrunner* package to be installed.

SysDiag tool provides DDR memory information, MCDRAM information, and PCI-E information. It also provides temperature and performance state information of the CPU.

SysDiag tool can execute stress diagnostics of the memory and the CPU by using the *threadrunner* tool.

For detailed information execute *SysDiag* tool help.

§

3 Linux Intel® Xeon Phi™ Processor Software installation, upgrade and uninstallation

This chapter describes how Intel® Xeon Phi™ processor software can be installed and configured.

Note: It is strongly recommended to read through this chapter before actually proceeding with installation to ensure that all required components and facilities are available. It is also strongly recommended that these installation steps be performed in the order they are presented.

3.1 Prerequisites

It is necessary that your system contain at least one Intel® Xeon Phi™ processor x200.

Intel® Xeon Phi™ processor software has been validated against specific versions of Red Hat* Enterprise Linux* (RHEL*) and SUSE* Linux* Enterprise Server (SLES*) as the main operating system. [Table 1](#) lists the versions of these operating systems.

Table 1 Host Operating Systems (Linux*) Intel® Xeon Phi™ processor software has been validated against

Supported OS Versions	Kernel Version
CentOS* 7.2	kernel-3.10.0-327.el7
SUSE* Linux* Enterprise Server 12	kernel-default-3.12.28-5.xppsl_1.3.3
SUSE* Linux* Enterprise Server 12 SP1	kernel-default-3.12.49-11.1.xppsl_1.3.3

To obtain the version of the kernel running on the host, execute:

```
$ uname -r
```

Note: Some packages that will be installed require access to the standard distribution packages and repositories. If you disabled any of standard repositories please consider re-enabling them to prevent *failed dependencies* issues. To get more information please check the information provided by your operating system documentation – for [Red Hat* Enterprise Linux*](#), and for [SUSE* Linux* Enterprise Server](#).

3.2 Root Access

Many of the tasks described in this document require administrative access privileges (i.e. root access). Verify that you have such privileges to the machines you will configure.

The use of *sudo* to acquire root privileges should be done carefully because its use may cause subtle and undesirable side effects. *Sudo* might not retain the non-root environment of the caller. This could, for example, result in use of a different *PATH* environment variable than expected, ending up with execution of the wrong code.

When *su* is used to become root, the non-root environment is (mostly) retained. (*HOME*, *SHELL*, *USER*, *LOGNAME* are reset unless the *-m* switch is given. See the *su* man page for details).

3.3 Distribution packages replacement

Please note, that installing Intel® Xeon Phi™ processor software will replace some of pre-installed packages that come with your OS distribution. Packages that will be replaced are listed below:

- *cpuid*
- *cpupower*
- *hwloc*
- *mcelog*
- *memkind*
- *perf-3.12* (SLES 12.0 only)

3.4 Installation

The following process will **not** replace your current Linux* kernel. Installation will add new kernel to grub, so it will be possible to choose the Intel® Xeon Phi™ processor software kernel on startup. Newly installed kernel contains information about Intel® Xeon Phi™ processor software version, possible kernel names are described in [Table 1](#).

3.4.1 Get the Intel® Xeon Phi™ Processor Software distribution

The latest Intel® Xeon Phi™ processor software distribution can be obtained from the software.intel.com. The software package releases are available in separate tar files for each supported OS. It is important to download a package for your operating system.

After downloading, un-tar the package:

```
$ tar xvf xppsl-<version>-<os>.tar
$ cd xppsl-<xppsl-version>/
```

3.4.2 Intel® Xeon Phi™ Processor Software Upgrade

Yum and *zypper* both support software upgrades and downgrades. Intel® Xeon Phi™ processor software from version 1.1.2 also supports updates. If you are on version 1.1.2 or above to install newer version of Intel® Xeon Phi™ processor software please follow steps described in [Section 3.4.4](#).

However, if your current software package is older than 1.1.2 and you would like to install newer version, it is necessary to perform a clean installation. Please follow instructions in [Error! Reference source not found.](#) and [3.4.4](#) to uninstall your version of Intel® Xeon Phi™ processor software and install a new one.

3.4.3 Intel® Xeon Phi™ Processor Software Uninstall

To check for a previously installed version of Intel® Xeon Phi™ processor software package execute:

```
$ rpm -qa | grep xppsl
```

Packages that correlate with Intel® Xeon Phi™ processor software will be listed and have to be uninstalled:

- Red Hat* Enterprise Linux*:

```
# yum remove [package-name]
```
- SUSE* Linux* Enterprise Server

```
# zypper rm [package-name]
```

3.4.4 Intel® Xeon Phi™ Processor Software Installation

Red Hat* Enterprise Linux*:

```
$ cd rhel<os-version>/
```

Install RPMs:

```
$ yum install x86_64/*rpm
```

SUSE* Linux* Enterprise Server:

```
$ cd suse<os-version>/
```

Install RPMs:

```
$ zypper install noarch/*rpm x86_64/*rpm
```

Note: In rare cases *zypper* might not be able to find all dependencies returning a *Failed dependencies* error message. The solution to this issue is manual installation of the missing software:

```
$ cd suse<os-version>
$ zypper install noarch/kernel-macros-3.12.28-4.6.xppsl_ \
<xppsl-version>.noarch.rpm noarch/ \
kernel-devel-3.12.28-4.6.xppsl_<xppsl-version>.noarch.rpm
$ zypper install noarch/*rpm x86_64/*rpm
```

If the following error occurs:

```
"The selected package 'kernel-devel-3.12.28-4.6.xppsl_<xppsl-
version>.noarch' from repository 'Plain RPM files cache' has
lower version than the installed one."
```

Please use the command below to force install the package.

```
$ zypper install --oldpackage kernel-devel-3.12.28- \
4.6.xppsl_<xppsl-version>.noarch
```

§

4 Rebuilding Linux* Intel® Xeon Phi™ Processor Software based Package Locally

Typically an RPM is pre-compiled and ready for direct installation. The corresponding source code can also be distributed. This is done in an SRPM package, which also includes the *SPEC* file describing the software and how it is built. The SRPM also allows the user to compile and modify the code.

The source code for user space tools is included in Intel® Xeon Phi™ processor software with both Red Hat* Enterprise Linux* and SUSE* Linux* Enterprise Server. The quickest way to handle the *.src.rpm files is to use the *rpmbuild* command. Please follow steps described below:

Go to your Intel® Xeon Phi™ processor software directory.

Red Hat* Enterprise Linux*:

```
$ cd rhel*/srpms/
```

SUSE* Linux* Enterprise Server:

```
$ cd suse*/srpms/
```

To build the RPM package, use the following command:

```
$ rpmbuild --rebuild <source_rpm_file>
```

§

§

5 Microsoft Windows* Intel® Xeon Phi™ Processor Software content

5.1 The hbmalloc Library

The *hbmalloc* library is designed to provide a programmer with access to the high bandwidth memory (MCDRAM) by allocating pages of MCDRAM memory. Provided API allows users to select allocation strategies, such as allocating with different guarantee levels of returned memory (preferred MCDRAM, guaranteed MCDRAM while allocation time, or locked on MCDRAM node memory) or page type (default or large pages).

§

6 Microsoft Windows* Intel® Xeon Phi™ Processor Software Installation

6.1 Intel® Xeon Phi™ Processor Software Installation

- 1) Unzip the `xppsl-<version>-Intel(R) Xeon Phi(TM) server-windows.zip` file.
- 2) Double-click the `xppsl-<version>-Intel(R) Xeon Phi(TM) server-windows.exe` file.
- 3) Follow the instructions on screen to complete the installation.
 - a. Select *Enable locking pages in memory* checkbox to add privilege `SeLockMemoryPrivilege` for the user (required to allocate large pages).
- 4) After the installation reboot of the system for the new settings to take effect.
- 5) If the Windows* security window appears select the **Always trust software from Intel®** checkbox.
- 6) The default installation path is `C:\Program Files\Intel\XPPSL\` it can be changed during installation.

6.2 Intel® Xeon Phi™ Processor Software Unattended Installation

- 1) In a command window, navigate to the directory that contains the setup files (For example: `C:\Users\<username>\Downloads\xppsl-<version>-Intel(R) Xeon Phi(TM) server-windows`)

```
User> cd "C:\Users\<username>\Downloads\xppsl-<version>-Intel(R) Xeon Phi(TM) server-windows"
```
- 2) Enter the following command:

```
User>"xppsl-<version>-Intel(R) Xeon Phi(TM) server-windows.exe" /s /v /qn /V"/quiet"
```

When using the unattended installation process, after entering the command it may take a few minutes to complete the installation.

To select *Enable locking pages* checkbox with unattended installation, `LOCKPAGES=1` parameter should be passed. Using `/norestart` parameter allows to postpone the system reboot.

```
User>"xppsl-<version>-Intel(R) Xeon Phi(TM) server-windows.exe" /s /v /qn /V"/quiet /norestart LOCKPAGES=1"
```

6.3 Intel® Xeon Phi™ Processor Software Upgrade

Upgrading the Intel® Xeon Phi™ processor software can be achieved by following instructions in the previous section. Users may choose to manually uninstall the previous version or let the installer automatically search and remove previous release prior to installing the latest one.

6.4 Intel® Xeon Phi™ Processor Software Uninstall

To uninstall the software stack open the **Control Panel**, choose **Programs and features** and remove the "*Intel(R) Xeon Phi(TM) server*" application.

§

7 Known Issues

1. Package `'debuginfo'` type conflicts with distribution/upstream packages
2. Package `xppsl-hwloc-devel` requires enabling RHEL* 7 subscription.
3. Package `xppsl-hwloc-devel` can break Intel® Xeon Phi™ processor software installation due to missing dependency `"pkgconfig(libpciaccess)"`.

This dependency cannot be satisfied by using RHEL* 7 DVD. Registering and enabling RHEL* subscription is required. To enable subscription please refer to RHEL* 7 user guide. This behavior occurs also for distribution `hwloc-devel` package. Missing package name for RHEL* 7.1 is `"libpciaccess-devel-0.13.1-4.1.el7.x86_64"`.

4. Package `xppsl-hwloc` does not update and needs to be reinstalled manually.
5. The `hbmalloc` library does not guarantee to allocate memory from the closest MCDRAM node when SNC-2 or SNC-4 Memory Mode is used.
6. The `hwloc` memory side cache discovery might fail when SELinux MLS policy is enforced. Install the `hwloc` policy module to mitigate this issue. Please note, that this module requires the `hwloc-dump-hwdata` files to be present in `/var/run/hwloc`.

Prerequisites:

- `policycoreutils` with SELinux scripts
- `selinux-devel` to build policy.

Use the following command to check if the `hwloc` module is installed:

```
semodule -l | grep hwloc
```

Build it manually in case it is missing from your system. It is required to obtain the policy from the SELinux repo:

```
git clone https://github.com/TresysTechnology/refpolicy-contrib
cd refpolicy-contrib
make -f /usr/share/selinux/devel/Makefile hwloc.pp
```

Run the following command to install the module:

```
semodule -i ./hwloc.pp
```

7. Performance comparisons between RHEL* 7.2 and SLES* 12 SP1 based on the STREAM benchmark revealed that memory transfers to/from MCDRAM in SLES* are ~4% faster:
 - SLES* 490 GB/s
 - RHEL* 470 GB/s

Booting RHEL* 7.2 in the tickless mode will rectify this difference. For more information please see *RedHat_tickless_xppl.pdf*.

§

8 Linux Kernel Support for Intel® Xeon Phi™ Processor x200 Product Family

The Intel® Xeon Phi™ processor x200 product family requires changes to various pieces of the current Linux* distribution; these changes are being released as patches and RPM source/binary packages, providing a specific version of the Linux* kernel, user space libraries and other utilities.

These changes are planned to be released as part of the associated open source projects. In addition, Intel® is working with Linux* vendors to provide support for the processor.

8.1 Overview

Linux* vendors, such as Red Hat* and SUSE*, take the power of open source software and make it available for the enterprise through *distributions* like Red Hat* Enterprise Linux* (RHEL*) [1] or SUSE* Linux* Enterprise Server (SLES*) [2]. In addition to collecting a set of components, Linux* vendors also test and certify their entire distribution and provide support.

A Linux* distribution includes a Linux* kernel, and several other important pieces of open source software such as GNU shell utilities, compilers (*gcc*, *binutils*, etc) and tools/libraries (*mcelog*, *hwloc*, etc), daemons, the graphical desktop (X server) and bootloaders like GRUB. Individual vendors also include software built in-house by that company. All of these pieces come together as a single product we think of as the operating system (OS). Additionally, companies like Red Hat* and SUSE* patch the source code in their distributions by picking up bug fixes (for functional, performance or security related issues), perform extensive testing to certify the entire distribution, and provide support (assurance) in case their customers encounter problems.

The Linux* upstream kernel from <http://www.kernel.org> undergoes many changes between the day the base version is selected by a vendor for inclusion in a particular distribution release and the day that release is shipped. [Figure 1](#) tries to depict how a Linux* kernel for a release of a distribution such as RHEL*/SLES* is created.

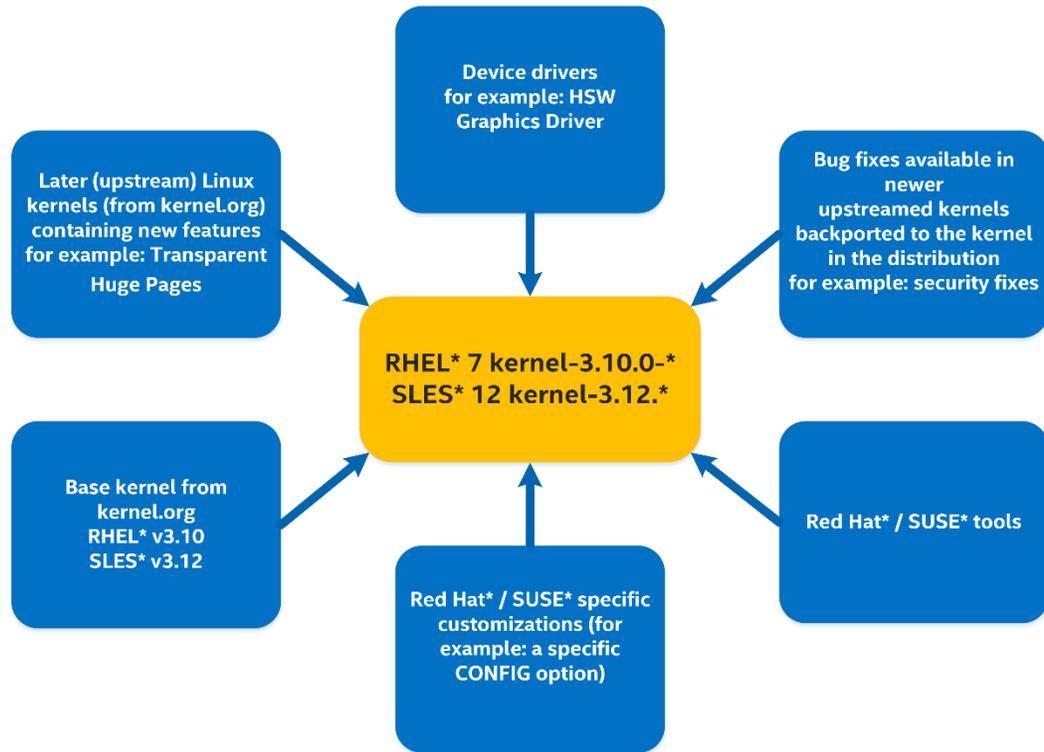

Figure 1 Components of a Linux* Distribution

The URL below captures current and planned RHEL releases along with the specific base Linux* kernel version for each release: <https://access.redhat.com/articles/3078>

An article discussing how different Linux* vendors construct their distributions can be found at the following URL <http://lwn.net/Articles/486304/>

8.2 Huge pages

8.2.1 Overview

Linux* systems support 2 MB and 1 GB huge pages, which can be allocated at boot or at runtime. Huge pages can significantly increase performance, particularly for large memory and memory-intensive workloads.

When huge pages are allocated during boot time, they are distributed equally between nodes. Runtime allocation allows the system administrator to choose which NUMA node to allocate those pages from. However, runtime page allocation can be more prone to allocation failure than boot time allocation due to memory fragmentation.

8.2.2 Huge Pages on Red Hat* Enterprise Linux*

Boot time mode:

1G huge pages on boot-time mode are enabled by default in Red Hat* Enterprise Linux* kernel. To allocate different sizes of huge pages at boot time, use the following command, specifying the number of huge pages. This example allocates 4 1 GB huge pages and 1024 2 MB huge pages:

```
'default_hugepagesz=1G hugepagesz=1G hugepages=4 hugepagesz=2M
hugepages=1024'
```

Change this command line to specify a different number of huge pages to be allocated at boot.

Runtime mode:

Huge pages could be also allocated in the runtime mode on RHEL* systems. To allocate them use following command:

```
# echo <number_of_pages> > sys/devices/system/node/node[0-9]*/hugepages/hugepages-<size_in_bytes>/nr_hugepages
```

8.2.3 Huge Pages on SUSE* Linux* Enterprise Server

Boot time mode:

The default size of Huge Page in SLES* is 2 MB. To enable Huge Pages bigger than default size additional configuration is required. Boot time mode distribute huge pages equally between the nodes.

To allocate different sizes of huge pages at boot time, use the following kernel boot parameters, specifying the number of huge pages. This example allocates 4 1 GB huge pages and 1024 2 MB huge pages:

```
'hugepagesz=1G hugepagesz=1G hugepages=4 hugepagesz=2M
hugepages=1024'
```

Change this command line to specify a different number of huge pages to be allocated at boot.

Runtime mode:

Be advised, that default SLES* kernel is not supporting huge pages in real-time mode. To enable this feature it is necessary to install additional kernel patches, and rebuild kernel with following lines in the kernel *config*:

```
CONFIG_CMA=y
CONFIG_CMA_DEBUG=n
```

Patches to apply:

Kernel Commit SHA	Patch name
bae7f4a	hugetlb: add hstate_is_gigantic()
a7407a2	hugetlb:update_and_free_page(): don't clear PG_reserved bit
1cac6f2	hugetlb:move helpers up in the file
944d9fe	hugetlb:add support for gigantic page allocation at runtime

To allocate Huge pages use following command:

```
# echo <number_of_pages> > sys/devices/system/node/node \
[0-9]*/hugepages/hugepages-<size_in_bytes>/nr_hugepages
```

8.2.4 Allocate all MCDRAM for 1G Pages

To allocate all MCDRAM for 1G pages is necessary to do following commands:

- Set *Treat MCDRAM as Hotplug node to enabled*. This can be enabled by setting a corresponding option in BIOS.
- Add kernel command line "*movable_node*" – it allows a node to have only movable memory. This option allows the following two things: when the system is booting, node full of *hotpluggable* memory can be arranged to have only movable memory so that the whole node can be hot-removed (specifying the *movable_node* boot option is required). After the system is up, the option allows users to online all the memory of a node as movable memory so that the whole node can be hot-removed. Users who do not use the memory *hotplug* feature can leave this option on since they do not specify *movable_node* boot option, or they do not online memory as movable.

8.3 Red Hat* Enterprise Linux* Distribution Options

Linux* support for the processor can be accomplished through the selection of different options. The following sections elaborate on each option in detail with their pros and cons, sorted from easiest to hardest from the end user perspective.

Each section contains a table that describes whether a particular feature is usable (noted as "Enabled" column) by relying on architectural approach or has been optimized with the processor specific parameters. The "Vendor support" row is listed for referencing if the option will likely void a support contract with a Linux* vendor; final word on contract validity is up to the vendor.

8.3.1 Intel® Xeon Phi™ Processor x200 Optimized RHEL* Distribution

Definition: By general availability of the processor, most if not all patches will be included in the RHEL* 7.3 distribution. (Additional patches that are

not part of RHEL* 7.3 will be available on <http://www.intel.com>. These patches are not required, but if used will provide optimal processor support. Note that applying those patches may void the support contract with the OS vendor

Pros: All the patches required to optimally support the processor features are part of the default installation. The customer gets support from the Linux* vendor and receives qualifications needed from that vendor.

Cons: Additional work may be required to port applications, scripts, etc. from an older RHEL* version to RHEL* 7.3. Earlier versions of RHEL* 7.X may contain some of the patches i.e. RHEL* 7.2 contains AVX-512 patch.

Feature	Status
AVX-512	Supported
Power Management	Supported
Performance Measurement Unit (PMU)	Supported
EDAC	Supported
Turbostat	Supported
KVM Virtualization	Supported
XEN Virtualization	Not supported

8.4 SUSE* Linux* Enterprise Server Distribution Options

8.4.1 Intel® Xeon Phi™ Processor x200 Optimized SLES* Distribution

Definition: By general availability of the processor, most if not all patches will be included in the SLES* 12 SP2 distribution. (Additional patches that are not part of SLES* 12 SP2 will be available on <http://www.intel.com>. These patches are not required, but if used will provide optimal processor support, but may void the support contract with the OS vendor)

Pros: All the patches required to optimally support the processor features are part of the default installation. The customer gets support from the Linux vendor and receives qualifications needed from that vendor.

Cons: Additional work may be required to port applications, scripts, etc. from an older SLES* version to SLES* 12 or newer. SLES* 12 SP1 will contain only AVX-512 patch.

Feature	Status
AVX-512	Supported
Power Management	Supported
Performance Measurement Unit (PMU)	Supported
EDAC	Supported
Turbostat	Supported
KVM Virtualization	Unconfirmed*
XEN Virtualization	Unconfirmed*
CPU enumeration	Supported
Coretemp	Supported
Memory management	Supported
memkind	Supported
mcelog	Supported
hwloc	Supported
rasdaemon	Supported
cpuid	Supported

* SLES 12.2 is still in BETA phase and some features may not be integrated

8.4.2 SLES* 12 with an Intel®-Provided Kernel.

Definition: The customer installs an Intel® provided kernel, based on SLES* 12, which contains all the processor kernel patches.

Pros: Allows customers to do early work to utilize all the new features of the processor before their Linux* vendor releases a processor enabled distribution. Also allows customers who are locked into using a version of SLES* with no processor enabling, to utilize the processor's full potential.

Cons: The use of a kernel different from the one provided by the Linux* vendor may void the support contract with the OS vendor.

9 User Space Components not delivered with Intel® Xeon Phi™ Processor Software

9.1 Development Tools

User space components like *gcc*, *binutils* and *gdb* have been updated to include support for AVX-512 code. However, the versions of these components shipped in a Linux* distribution is selected by the Linux* vendor and might not include the updated versions.

For such components, the following options are available:

9.1.1 Intel® Xeon Phi™ Processor Enabled OS Distribution Versions

These versions of RHEL* will have full user space support for AVX-512 processor features. The customer will get support from the Linux* vendor and receive any qualifications required from that vendor.

9.1.1.1 Red Hat Developer Toolset (DTS) Version 3

For customers using Red Hat*, DTS is available at https://access.redhat.com/documentation/en-US/Red_Hat_Developer_Toolset/3/index.html, and provides optional versions of *gcc*, *gdb* and *binutils*. These optional versions are not replacements for the main tools in the distribution, but provide alternate versions of *gcc* 4.9, *binutils* 2.24 and *gdb* 7.8, which are enabled for AVX-512. DTS is available for RHEL* 6 and RHEL* 7

9.1.2 Processor Enabled Versions of the User Space Components

The customer can build the open source versions of *gcc*, *binutils* and *gdb* which support AVX-512 and install them as an optional tool chain. By using upstreamed versions, customers can get support for those components from the developer community.

§

10 *Conclusions*

The addition of new hardware support provided by an enterprise Linux* distribution or Microsoft Windows* is a staged process, where a number of variables come into play. The options provided in this document are not definitive and are meant to serve only as a guide; ultimately the customer needs to decide if any of the options described in this paper fits their needs.
